1. Introduction

\textit{De novo} microdeletions/microduplications encompassing one or few genes are an easy way to identify genes involved in developmental disorders. Interstitial microdeletions involving the 7p22.1 chromosomal region are very rare, since were recently described in only few cases with developmental delay/intellectual disability, short stature and microcephaly (Shimojima et al., 2016). From a molecular point of view, two of the five patients showed a very small deletion, that allowed the authors to identify a genomic region encompassing the FBLX18, ACTB, FSCN1, RNF216 and ZNF815P genes as the “minimal critical region” (MCR). From a medical point of view, since the clinical relevance of the FBLX18, FSCN1 and ZNF815P genes was unknown, the authors focused their attention on the remaining two. In particular, they proposed the haploinsufficiency of \textit{ACTB} as responsible for the clinical manifestations of 7p22.1 microdeletions.

Here, we describe a patient with developmental delay, short stature, microcephaly and dysmorphic features carriers of the smallest interstitial \textit{de novo} microdeletion in the chromosomal region 7p22.1 reported to date encompassing the FBLX18 and \textit{ACTB} genes. We compared molecular findings as well as clinical presentation of our patient and previously reported cases with deletions involving the \textit{ACTB} gene discussing its role in the etiology of the observed clinical phenotype.
2. Clinical report

The patient, a female, is a bigeminy twin of a bicornial-biamniotic pregnancy achieved by intra cytoplasmic sperm injection (ICSI). Family history was unremarkable for any genetic disorders and parents were not consanguineous. She was born preterm at 33 weeks of gestation by elective cesarean section because maternal cholestatis. Birth weight was 1400 g (10th centile), length was 39 cm (3rd-10th centile) and occipitofrontal circumference (OFC) was 28.2 cm (< 3rd centile). Apgar scores were 5 and 7 at 1 and 5 min, respectively. She was admitted for prematurity to Neonatal Intensive Care Unit for four weeks and required ventilation because respiratory distress. Clinical geneticist evaluated the patient at 23 months of age (corrected age 21 months). Motor developmental milestones were slight delayed, expressive language was limited to few words. Her medical history was positive for failure to thrive, celiac disease was excluded, hematocrit and thyroid function exams were in normal range. Her growth parameters were all < 3rd centile: length was 72.3 cm, weight was 6950 kg and OFC was 44 cm. Physical examination revealed distinctive dysmorphic features with frontal bossing, bitemporal narrowing, prominence of metopic suture, large anterior fontanelle, high anterior hairline, lateral sparse eyebrows, long eyelashes, long philtrum, thin lips and pointed chin. In addition, moderate hypotonia, mild joint laxity and bilateral clinodactyly of the 5th finger (Fig. 1) were noted. Electroencephalogram (EEG) did not show any abnormalities, and echocardiogram was normal. Abdominal ultrasound showed mild unilateral pyelectasis. Ophthalmological evaluation detected hypermetropia and exotropia. Audiological assessments were in normal range. Cerebral magnetic resonance imaging (MRI) did not demonstrate structural anomalies.

In the same occasion was evaluated also her twin. Length was 78.5 cm (3rd-10th centile), weight was 8500 kg (< 3rd centile), occipitofrontal circumference was 44.7 cm (3rd-10th centile). No dysmorphic features like her sister were noted. Her neuromotor development was according to age.

3. Materials and methods

SNP array based Copy Number Variations (CNVs) analysis was performed on genomic DNA extracted from peripheral blood lymphocytes of the patient, her sister and her parents, after obtaining written informed consent, using the CytoScan HD Array (Affymetrix, Santa Clara, CA, USA) as previously described (Palumbo et al., 2014). Data analysis was performed using the Chromosome Analysis Suite software version 3.1 (Affymetrix, Santa Clara, CA, USA). A CNV was validated if at least 25 contiguous probes showed an abnormal log2 ratio. The clinical significance of each CNV detected was assessed by comparison with an internal database of 3500 patients studied in our laboratory by SNP array since 2010 with a diagnosis of syndromic/non-syndromic neurodevelopmental disorders.

Fig. 1. The patient at 23 months. Detailed clinical description is reported in the text.

Fig. 2. Results of chromosomal microarray analysis in the patient, her parents and her sister. Copy number state of each probe is drawn along chromosome 7 from 5200 to 5900 kb. The red box indicate the de novo interstitial microdeletion identified in the genomic profile of the patient.
