Abstract Hyperbilirubinaemia is one of the most frequent causes of hospital readmission during the first week of life. Its detection is still a big challenge, mainly due to the early discharge from the hospital that can be associated with a delay of the diagnosis.

The identification of those newborns at risk of developing significant hyperbilirubinaemia is one of the main priorities in the public health care system.

An approach to the management of newborn jaundice is presented in this article, following the recommendations based on the medical evidence and on the opinion of the Standards Committee of the Spanish Society of Neonatology.

Introduction

Hyperbilirubinaemia is a common medical problem and is usually benign in term and late preterm (PT) newborns. It is the most frequent cause of hospital readmission in the first week of life. Early discharge of healthy newborns, especially those in who breastfeeding (BF) has not been fully established, may be associated with delays in its diagnosis. In certain circumstances (glucose-6-phosphate dehydrogenase [G6PD] deficiency, sepsis, etc.) severe hyperbilirubinaemia may occur and can produce brain damage despite appropriate intervention.

Much of the management of neonatal jaundice is based on low-grade evidence. This review proposes an approach to its management through evidence-based recommendations.

Methods

We performed a literature review searching the PubMed database (MeSH) for the following keywords: jaundice, hyperbilirubinaemia, newborn, late preterm, guidelines.

We graded the quality of the evidence with the classification established by the Center of Evidence-Based Medicine (http://www.cebm.net) (Table 1) and the strength of the recommendation based on the guidelines of the Canadian Task Force on Preventive Health Care (Table 2).

Results

Prevention strategies

Breastfed newborns are at greater risk of developing hyperbilirubinaemia than newborns fed artificial formula. However, the known risks of acute bilirubin encephalopathy are very small when weighed against the benefits of BF. The primary approach to mitigating the hyperbilirubinaemia associated to BF is to ensure that BF is successful. An insufficient energy intake and/or dehydration associated with inadequate BF may contribute to the development of hyperbilirubinaemia due to an increase in the enterohepatic circulation of bilirubin.
