A new concept and method of imposing imprecise (fuzzy) input and output data upon the conventional linear regression model is proposed. Under the considerations of fuzzy parameters and fuzzy arithmetic operations (fuzzy addition and multiplication), we propose a fuzzy linear regression model which has the similar form as that of conventional one. We conduct the $h$-level (conventional) linear regression models of fuzzy linear regression model for the sake of invoking the statistical techniques in (conventional) linear regression analysis for real-valued data. In order to determine the sign (nonnegativity or nonpositivity) of fuzzy parameters, we perform the statistical testing hypotheses and evaluate the confidence intervals. Using the least squares estimators obtained from the $h$-level linear regression models, we can construct the membership functions of fuzzy least squares estimators via the form of "Resolution Identity" which is well-known in fuzzy sets theory. In order to obtain the membership degree of any given estimate taken from the fuzzy least squares estimator, optimization problems have to be solved. We also provide two computational procedures to deal with those optimization problems.

1. Introduction

In the real world, the data sometimes cannot be recorded or collected precisely due to human errors, machine errors or some other unexpected situations. For instance, the water level of a river cannot be measured in an exact way because of the fluctuation, and the temperature in a room is also not able to be measured precisely because of similar reasons. With this situation, fuzzy sets theory is naturally an appropriate tool in statistical models when fuzzy data have been observed. The more appropriate way to describe the water level is to say that the water level is around 30 m. The phrase "around 30 m" can be regarded as a fuzzy number 30. This is the main concern of this paper.

In the approach of Tanaka et al. (1982), they considered the $L-R$ fuzzy data and minimized the index of fuzziness of the fuzzy linear regression model. Redden and Woodall (1994) compared various fuzzy regression models and gave the difference between the approaches of fuzzy regression analysis and conventional regression analysis. They also pointed out some weakness of the approaches proposed by Tanaka et al. Chang and Lee (1994) also pointed out another weakness of the approaches proposed by Tanaka et al. Peters (1994) introduced a new fuzzy linear regression models based on Tanaka’s approach by considering the fuzzy linear programming problem. Moskowitz and Kim (1993) proposed a method to assess the $H$-value in a fuzzy linear regression model proposed by Tanaka et al. Wang and Tsaur (2000) also proposed a new model to improve the predictability of Tanaka’s model.

In this paper, we propose a fuzzy linear regression model, and then the $h$-level linear regression models will be created by taking the $h$-level set of fuzzy linear regression model. We shall see that the $h$-level linear regression models are conventional linear regression models. Therefore, the statistical techniques proposed in the conventional linear regression analysis can be invoked to discuss the $h$-level linear regression models.

For the least squares sense, Chang (2001) proposed a method for hybrid fuzzy least squares regression by defining the weighted fuzzy-arithmetic and using the well-accepted least squares fitting criterion. Celmins (1987, 1991) proposed a methodology for the fitting of differentiable fuzzy model function by minimizing a least squares objective function. Chang and Lee (1996) proposed a fuzzy regression technique based on the least squares approach to estimate the modal value and the spreads of $L-R$ fuzzy number. Jajuga (1986) calculated the linear fuzzy regression coefficients using a generalized version of the least squares method by considering the fuzzy classification of a set of observations and obtaining the
2. Fuzzy numbers

Let $X$ be a universal set and $A$ be a subset of $X$. Then the indicator (characteristic) function $1_A$ defined by

$$1_A(x) = \begin{cases} 1 & \text{if } x \in A \\ 0 & \text{otherwise} \end{cases}$$

can be used to represent the subset $A$ of $X$. A fuzzy subset $\tilde{A}$ of $X$ proposed by Zadeh (1965) is defined by its membership function $\tilde{\xi}_A(x)$ on $X$, such that for each $x \in X$, the membership degree $\tilde{\xi}_A(x)$ of $x$ in $A$ indicates how much $x$ is in $A$. We see that the concept of membership function is an extension of the indicator function $1_A$ of $A$, since the indicator function $1_A$ can also be regarded as a membership function of $A$. In this case, the indicator function is sometimes called a crisp function in the fuzzy sets theory.

Let $X$ be endowed with a topological structure $\tau$. We denote by $A_\tau = \{ x : \tilde{\xi}_A(x) \geq h \}$ the $h$-level set of $A$ for $h \in (0,1]$, and $A_\text{no}$, called as support of $A$, is taken as the closure of the set $\{ x : \tilde{\xi}_A(x) > 0 \}$. $\tilde{A}$ is called a normal fuzzy set if there exists an $x$ such that $\tilde{\xi}_A(x) = 1$, and is called a convex fuzzy set if $\tilde{\xi}_A(x + \lambda y) \geq \min(\tilde{\xi}_A(x), \tilde{\xi}_A(y))$ for $x, y \in X$, $\lambda \in [0,1]$, i.e., $\tilde{\xi}_A$ is a quasi-concave function (Ref. [Royden (1968) & Rudin (1986)]).

Throughout this paper, the universal set $X$ is assumed to be a real number system $\mathbb{R}$ endowed with a usual topology. Let $f$ be a real-valued function defined on $\mathbb{R}$. Then $f$ is said to be upper semicontinuous if $f(x) \geq \liminf x \to a f(x)$ for each $a$. Equivalently, $f$ is upper semicontinuous at $y$ if and only if $\forall \varepsilon > 0, \exists \delta > 0$ such that $|x - y| < \delta \implies f(x) < f(y) + \varepsilon$ (Ref. Royden (1968) & Rudin (1986)).

Let $\tilde{a}$ be a fuzzy subset of $\mathbb{R}$. Then $\tilde{a}$ is called a fuzzy number if the following conditions are satisfied:

- $\tilde{a}$ is a normal and convex fuzzy subset of $\mathbb{R}$.
- Its membership function $\tilde{\xi}_a$ is upper semicontinuous.
- The $h$-level set $\tilde{a}_h$ is bounded for each $h \in [0,1]$.

From Zadeh (1965), $\tilde{A}$ is a convex fuzzy subset of $\mathbb{R}$ if and only if its $h$-level set $\tilde{A}_h = \{ x : \tilde{\xi}_A(x) \geq h \}$ is a convex subset of $\mathbb{R}$ for all $h \in [0,1]$ ($\tilde{A}$ is a convex subset of $\mathbb{R}$ if and only if $\forall x_1, x_2 \in A$ and $t \in (0,1)$, therefore if $\tilde{a}$ is a fuzzy number, then the $h$-level set $\tilde{a}_h$ is a closed and bounded subset of $\mathbb{R}$ from conditions (ii) and (iii), and a convex subset of $\mathbb{R}$ from conditions (i); that is, $\tilde{a}_h$ is a closed interval in $\mathbb{R}$. The $L$-level set of $\tilde{a}$ is then denoted by $\tilde{a}_L = [a_L, a_U]$. We also see that $a_L$ and $a_U$ are continuous with respect to $h$ (i.e., $h \mapsto a_L$ and $h \mapsto a_U$) are continuous functions for a fixed fuzzy number $\tilde{a}$, since its membership function is upper semicontinuous. The following proposition is useful for further discussions.

**Proposition 2.1** (Zadeh et al. (1975)(Resolution Identity)). Let $\tilde{A}$ be a fuzzy subset of $X$ with membership function $\tilde{\xi}_A$, and the $h$-level set $\tilde{A}_h = \{ x : \tilde{\xi}_A(x) \geq h \}$ of $\tilde{A}$ be given. Then the membership function can be represented as

$$\tilde{\xi}_A(x) = \sup_{h \in [0,1]} h \cdot 1_{\tilde{A}_h}(x),$$

where $1_{\tilde{A}_h}$ is the indicator function of (crisp) set $\tilde{A}_h$.

$\tilde{a}$ is called a crisp number with value $m$ if its membership function is given by

$$\tilde{\xi}_a(x) = \begin{cases} 1 & \text{if } x = m \\ 0 & \text{otherwise} \end{cases}$$

It is denoted by $\tilde{a} \equiv \tilde{1}_m$. We also see that $\langle \tilde{1}_m \rangle = \langle \tilde{1}_m \rangle^U = m$ for all $h \in [0,1]$.

Let $\tilde{a}$ be a fuzzy number. Then $\tilde{a}$ is called nonnegative if $\tilde{\xi}_a(x) \geq 0$ for all $x < 0$ and nonpositive if $\tilde{\xi}_a(x) \leq 0$ for all $x > 0$. It is obvious that $a_L$ and $a_U$ are nonnegative real numbers for all $h \in [0,1]$ if $\tilde{a}$ is a nonnegative fuzzy number, and $a_U$ and $a_L$ are nonpositive real numbers for all $h \in [0,1]$ if $\tilde{a}$ is a nonpositive fuzzy number.

Let $\circ$, be any binary operation $\circ$ or $\circ$ corresponding to the operations $\oplus = +$ or $\ominus$. Then we have the following well-known results.

**Proposition 2.2.** Let $\tilde{a}$ and $\tilde{b}$ be two fuzzy numbers. Then $\tilde{a} \oplus \tilde{b}$ and $\tilde{a} \ominus \tilde{b}$ are also fuzzy numbers. Furthermore, we have

$$\langle \tilde{a} \oplus \tilde{b} \rangle_h = \begin{cases} a_L + b_L, & a_U + b_U \\ \min \{ a_L b_L, a_U b_U \}, & \max \{ a_L b_U, a_U b_L \} \end{cases}$$

using the extension principle in Zadeh et al. (1975), where the operations $\oplus = +$ or $\ominus$ corresponding to the operations $\circ = +$ or $\ominus$. Then we have the following well-known results.
