Abstract
Objectives: To investigate clinical and psychological features of patients with anorexia nervosa (AN) with a previous history of bulimia nervosa.
Method: Three hundred thirty-three patients with a full diagnosis of AN were assessed by the Structured Clinical Interview for the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, the Eating Disorders Inventory, and the Hopkins Symptom Checklist.
Results: Twenty-four patients (7%) reported a previous diagnosis of bulimia nervosa and were compared with a control group of 48 patients without a history of bulimia, matched for diagnostic subtype. Among the patients with a history of bulimia nervosa, 11 were of the restricting type and 13 of the binge eating/purging type. Among restricting anorexic patients, those with a history of bulimia reported greater age of onset, more psychiatric symptoms, more family psychiatric morbidity, and a higher rate of sexual abuse. On the contrary, among patients with the AN bingeing-purging subtype, the presence of a previous bulimia nervosa was not associated with any of the investigated variables.
Conclusions: Patients with restricting AN who report a history of previous bulimia nervosa are not frequent among those referring to an outpatient eating disorders unit. However, our findings in this small group of subjects confirm that a lifetime history of bingeing and purging in patients with eating disorder, irrespective of when it occurs, is always associated with more psychopathology compared with those restricting patients with AN who have never had a period of bingeing and purging.

1. Introduction
A large proportion of patients with eating disorder tend not to adhere to their Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV) diagnosis over time but migrate between the diagnostic categories [1,2]. One of the most common shifts from one diagnosis to another is from anorexia nervosa (AN) to bulimia nervosa (BN) [1,3]. It has been estimated that about 30% of patients with restricting AN develop BN [4,5]. In an epidemiological study performed on a general female population sample, about 33% of BN cases reported an episode of AN or subthreshold AN preceding the development of BN [2]. BN patients with a history of AN seem more often to have a lifetime comorbidity with anxiety disorders [3,6], to weigh less [3,7], to vomit more frequently, and to report an earlier age of onset of their bulimic symptoms [8].

Kassett et al [9] observed that the reverse shift is also possible. However, the development of AN among subjects who suffer from BN seems uncommon [10]. That is probably why this peculiar evolution between diagnostic categories has received little attention in the literature.

The main aim of the present study is to investigate the prevalence and clinical features of AN patients with a history of bulimia.

2. Methods
2.1. Sample
We examined the records of all patients with a full diagnosis of AN, according to DSM-IV (APA, 1994), who consecutively referred to our eating disorders outpatient unit from July 1992 to December 1999. Criteria of exclusion were the lifetime presence of a diagnosis of a schizophrenia-spectrum disorder, of a substance/alcohol dependence disorder, and of an endocrinological illness (such as diabetes or hyperthyroidism). All the criteria of inclusion were
fulfilled by 333 AN patients (221 restricting type and 112 binge eating/purging type). Among these subjects, we checked the presence of a diagnosis of lifetime BN (according to the DSM-IV criteria), excluding those who presented amenorrhea and/or a body mass index (BMI) lower than 17.5 at the time of BN. AN subjects with a history of sexual abuse, presence of alcohol/substances abuse, history of suicide attempts, family psychiatric morbidity, and BMI after 3 months of treatment.

### 2.3. Statistical analysis

SPSS software (SPSS Inc, Chicago, Ill) was used. χ² (with Yates’ continuity correction for 2 × 2 tables) and t test were used to compare groups. Given the explorative nature of the study, we did not use any correction of P values for multiple comparisons.

### 3. Results

Of the 333 AN patients who fulfilled the criteria of inclusion, 24 (7%) reported a history of BN according to the DSM-IV criteria. Of the 24 AN patients with previous BN, 11 (5% of restricting AN patients) were AN cases of the restricting type, whereas 13 belonged to the binge eating/purging type (12% of binge eating/purging type AN patients). In most cases, the episode of BN was of the purging type (71%). To assess the presence of trends in the
