1. Introduction

Drug use causes severe public health and social problems (Zhao et al., 2004). As of 2007, about 40% of the 700,000 estimated HIV cases in China could be attributed to injecting drug use (State Council AIDS Working Committee Office, China, & UN Theme Group on HIV/AIDS in China, 2007). The number of registered drug users has increased from 70,000 in 1990 to 1.27 million in 2009 (Yin et al., 2010). The actual number of drug users is estimated to be several times higher than that of the officially registered (Kulsudjarit, 2004). Heroin is the most popular drug choice, favored by over 85% of drug users in China (Sullivan & Wu, 2007).

Compulsory detoxification has been used as one of the main means of illicit drug control in China (Sullivan & Wu, 2007). Arrested drug users will be kept in compulsory detoxification centers for three to six months, while those who have been arrested repeatedly will be detained in re-education centers for one to three years (Sullivan & Wu, 2007). Previous studies have shown that compulsive detoxification in China was ineffective in reducing drug use (Liu et al., 2006). There are however, very few low-cost voluntary detoxification centers operating in China.

Methadone Maintenance Treatment (MMT) is an evidence-based and effective treatment for heroin dependence (No authors listed, 1998). In the last few decades, numerous studies have demonstrated the efficacy of MMT in avoidance of heroin dependence, overdoses, deaths, illegal activities, HIV-related risk behaviors, and improving the overall wellbeing of heroin users (Clausen, Ancheresen, & Waal, 2008; Gowing, Farrell, Bornemann, Sullivan, & Ali, 2008; Marsch, 1998; Mattick, Breen, Kimber, & Davoli, 2009). Methadone has been used as a means of detoxification in the nineties in China (Lu & Wang, 2008). MMT programs however, started only in 2004 when the Chinese government piloted the first eight MMT clinics in five provinces (Pang et al., 2007). After positive evaluation results, MMT has become a key component of China’s drug control and HIV prevention strategies, and has been expanded into a nationwide program encompassing 680...
MMT is a replacement therapy, rather than a curative treatment (Joseph, Stancliff, & Langrod, 2000). Its effectiveness rests upon a long-term or even lifetime treatment with appropriate dosages (Joseph et al., 2000). However, MMT-related misconceptions are prevalent among drug users. In the literature, the most popular misconceptions included that MMT is harmful to users' health (e.g., 'methadone gets into bones', 'methadone rots your teeth') (Peterson et al., 2010; Winstock, Lea, Madden, & Bath, 2008), higher dosages of methadone are more harmful than lower dosages (Stancliff, Myers, Steiner, & Drucker, 2002), disagreement on the long-term nature of the treatment (Schwartz et al., 2008), and MMT users should get off MMT (Stancliff et al., 2002), among others. Almost all of these studies were conducted in North America, and so far there is no study investigating MMT users' misconceptions toward MMT in China.

Evidence has showed that peoples' perceptions about treatment would influence their compliance and treatment outcomes (Nelson-Zlupko, Dore, Kauffman, & Kaltenbach, 1996; Shen, Mcclellan, & Merrill, 2000; Siqueland et al., 2004; Zaller, Bazazi, Velazquez, & Rich, 2009). Misconceptions toward MMT may result in high drop-out rates. Studies among MMT clients showed that correct perceptions toward MMT were associated with longer durations of treatment and less psychiatric problems (Kasarabada, Hser, Boles, & Huang, 2002). In China, the number of MMT clinics is still on the rise, while previous studies have reported high drop-out rates of 40–60% within six-month periods (Chen et al., 2009; Li et al., 2009; Pang et al., 2007). It is crucial to understand Chinese MMT users' views about MMT in order to design interventions that are effective and culturally appropriate in order to improve MMT retention in China.

The present study investigated the prevalence of several MMT-related misconceptions among drug users who were newly admitted to three MMT clinics in China. Factors associated with these misconceptions were identified. We hypothesized that i) misconceptions toward MMT would be prevalent among MMT users, and ii) such misconceptions would be associated with MMT users' prior usage of methadone in voluntary drug detoxification centers, prior exposure to other HIV-related services, by whom the participant was introduced to use MMT and other factors such as the study site and the level of HIV-related knowledge.

2. Methods

2.1. Study sites and data collection

The study was conducted during May 2009 through April 2010 in three of the nine MMT clinics in Guangzhou, the capital city of Guangdong Province which has a population size of 9.94 million. The city ranks the second within the province in terms of the total number of reported HIV/AIDS cases, whilst there were 68,000 estimated drug users, most of whom were heroin users (Zhong, Xu, & Zhao, 2007). Inclusion criteria of this study were: 1) being an active heroin user, 2) being a registered local resident or possessing a temporary resident certificate, 3) being at least 18 years old, 4) no prior experience of being admitted to any MMT clinics, and 5) being newly admitted to the participating MMT clinic and had not yet taken any dose of methadone before the interview.

The two interviewers were trained in social work; being experienced in community-based drug rehabilitation and working with drug users. They approached newly admitted MMT users before their initiation of service, briefed them about the purpose and logistics of the study and assured them about data confidentiality and the voluntary nature of participation. Written informed consent was obtained before the participants were face-to-face interviewed in a private setting. A total of 307 newly admitted MMT users were invited to join the study, among whom 300 (97%) completed the interview. The study was approved by the Ethics Committee of School of Public Health, Sun Yet-sen University.

2.2. Measures

2.2.1. Background characteristics and other independent variables

Data on socio-demographic characteristics and service utilization (HIV voluntary counseling and testing [VCT], distribution of free condoms and HIV-related education materials) were collected. Five questions on HIV-related knowledge were asked (see footnotes in Table 1) and a dummy variable was created by counting the number of appropriate responses. Information was obtained regarding participants' history of drug use (duration of drug use, daily expenditure on drugs, experience with compulsive detoxification, experience in using methadone in voluntary drug detoxification centers, and by whom the participant was introduced to use MMT).

2.2.2. Assessment of MMT-related misconceptions

Four statements were used to assess MMT-related misconceptions: (1) 'MMT is intended primarily for detoxification'; (2) 'One could be completely detoxified and quit using methadone after using it for two to three months'; (3) 'MMT is a long-term or even lifetime treatment'; and (4) 'One should attempt to reduce its treatment dosage as methadone is harmful to one's health'. Agreement with Items 1, 2, 4 and disagreement with Item 3 were regarded as unfavorable misconceptions. A panel of researchers met and generated these items, basing on the results of our literature review and a pilot study interviewing 15 MMT users.

2.3. Statistical analyses

Univariate logistic regression models were fit separately to identify factors that were associated with the four misconception variables. Factors with $p<0.1$ were used as candidates for the respective stepwise logistic regression models. SPSS for Windows Version 17.0 was used for data analyses and $p<0.05$ was considered as statistically significant.

3. Results

3.1. Background characteristics of the participants

The majority of the participants (92.3%) were male; 74.1% were older than 35 years in age; 74% had attained post-secondary education; 48.3% were single and 69.3% were currently unemployed. Over 60% of the participants (60.9%) provided appropriate responses to all the five HIV-related knowledge items. About half (47%) of those had taken up VCT prior to admission and 38.6% had previously received HIV-related education materials and free condoms (Table 1).

On average, the duration of heroin use was 13.5 years, whilst 14.8% of the participants had used heroin for longer than 20 years. The average daily expenditure on heroin was 177 CNY (27 USD). Over 80% (85.9%) of the participants had previously been admitted to compulsive drug detoxification centers; 34.1% had ever used methadone for drug detoxification in voluntary drug detoxification centers (which were not MMT clinics). About one-third (33.9%) had not been introduced by anyone to use MMT.

3.2. Level of MMT-related misconceptions

Misconceptions were very prevalent among participants. The majority believed that MMT is intended primarily for detoxification (92.3%), that one could be completely detoxified and quit using methadone after using it for 2–3 months (64.2%), that MMT is not a long-term or even lifetime treatment (77.9%) and that one should attempt to reduce its treatment dosage as methadone is harmful to one's health (84.3%). Almost all participants (94%) exhibited responses...
