ABSTRACT

Database management has an important role to play in the management of data assets which are at the heart of every organization. In a fast moving technological era, where data is rapidly expanding, understanding the current best practices and procedures is important for continuous improvement. This paper investigates how databases are actually administered and identifies what practices and procedures are utilized throughout the database lifecycle. The paper highlights the demographics of people who manage database systems and the diverse requirements of database systems given the wide range of software and hardware available. The results of this paper show the breadth of issues relevant to database management. The paper concludes by showing where existing practice and procedures are not optimal, and by highlighting the complexities in the field.

1. Introduction

Database management is, at its heart, the administrative tasks associated with the storage, modification and retrieval of data held within a database management system (DBMS). Organizations today require impeccable database management in order to maintain a high quality of data, and for that data to be secure and available whenever it is required. The data for governments, banks, financial institutions etc. must also satisfy statutory legal requirements.

It has been well publicized that problems exist with the setting up and successful operation of important databases. An early report by De Blasis [8] highlighted problems with administration, organizational issues, new technology introduction, control and technical configuration. There are many reasons for these problems. The use of appropriate practices and procedures can have a significant impact on the availability, recoverability and quality of data used in the operations

of businesses. The diversity of an organization's domains and strategies can lead to a variety of practices and procedures.

Certain practices used by organizations can be considered "best practice". Best practices are frequently described as those which are recommended for carrying out actions for desirable outcomes (see Fig. 9). Best practices drive operational excellence and effectiveness [13]. Other key terms used here are: processes – "a series of actions or steps taken in order to achieve a particular end"; procedures – "an established or official way of doing something"; and methodology – "a system of methods used in a particular area of activity" (all definitions from Oxford Dictionaries [32]).

This paper presents the findings from a comprehensive survey which investigated to what extent best practices and procedures are utilized by the database community.

2. Background to the research

Database management has evolved over the last five decades, since the first functioning prototype DBMS [21], to become an integral part of most organizations' business. The majority of global organizations today cannot operate without a functioning database. Organizations increasingly

realize the value of the data that they hold and are beginning to draw more benefit from its analysis and mining [12]. Some examples of usage include shopping history to predict purchases [11], social media to predict trends [33], live mapping for disaster aid [16], the storage of the human genome to aid medical research [7], sensor data from CERN [34] and other data intensive scientific discoveries [22,23].

Changes in culture and everyday life have brought about the sharing of more information, and this has radically changed the usage of databases. New technologies such as cloud and virtualization enable a different operating model, one that allows organizations to share resources, but these new models add to the complexity of an already complicated activity.

The trend of rapidly increasing data volumes is being driven not only by the requirements of government and business to store more information, but also by the digitization of film and TV and the use of social media. Gantz and Reinsel [15] have estimated that the volume of all known data will have grown from 0.8 zettabytes (10^{21} bytes) in 2009 to 35 zettabytes in 2020. This is a mixture of both structured and unstructured data. Unstructured data, objects that have little or no identifiable structure, e.g. text, images, audio and video, were not previously considered within the database community. However this view has now changed within the industry as a whole. The Lowell Report [2], a summary of a gathering of academic database researchers' discussions on the state of database research, states that "Database needs are changing, driven by the internet and increasing amounts of scientific and sensor data" [2, p. 111].

The administration and management of this complex area would benefit from a better understanding of the extent to which best practices and procedures are utilized by the database community. However, that raises the question as to whether the adoption of best practice is constrained by the many interactions between the different interconnected aspects of the management of database systems.

The database management system (DBMS) itself is constructed of many components which can be considered to form a layered technical system. Typically, disparate organizational teams manage each layer independently. These teams have different sets of goals, together with a variety of approaches, and problems in operation which can occur due to the interconnections. This has increased the challenges of overall management.

Many organizations demand low cost infrastructure without jeopardizing functionality or operational ability. Database architecture, design and development are the foundation of any well designed DBMS. The database is continually evolving and adapting to the demands of the users, organizations and the global environment.

The management of the database and the data contained within it are often undertaken by different teams. Two separate functions were identified by Kahn [25, p. 794] as database administration and data administration. However, they have many interconnected components. Organizations' business requirements for data collection and manipulation appear to be driving the requirements for database management. The fields are gradually merging, and Mullins [31] proposed data administration practices and procedures to

address this, arguing that "when database administration is treated as a management discipline, the treatment of data within your organization will improve" [31, p. 9]. A management discipline is required to manage the successful operation of the databases. The management methods used for development and infrastructure projects has also changed. Historically, development projects have been dominated by Waterfall methodologies, but there has been some shift towards Agile methodologies to overcome Waterfall's inflexibility in relation to rapidly changing business requirements [37].

Changes to the database engine, structure and hardware all require practices and procedures to ensure that data is protected. The Independent Oracle Users Group (IOUG) has recently completed several surveys that aid in understanding the complexities of database systems. The IOUG report [28] entitled "Managing the Rapid Rise in Database Growth" identified the importance of database change management practices.

There are many current complexities related to data management and data administration, and as Aiken et al. [5] suggest, data management is still evolving. The Claremont report on database research [3, p. 65] highlighted concerns that are important to the community regarding the increasing technical scope, processes and keeping track of the field that is important to the community. Other surveys previously undertaken provided some insight, and highlighted the rise of database administration, with an unclear direction of the future path [5,17–19,27,30].

The survey reported here highlights the real world situation of the database community at present, and shares the current practices and procedures of the respondents.

3. The survey

The primary goal of the research was to investigate how databases were actually administered and to identify what practices and procedures were utilized throughout the database lifecycle. Further aims were to understand the demographics of people who manage database systems, and to investigate how they learned about best practice and whether any IT frameworks were used. As the database community is dispersed globally, the survey has sought to reflect this global nature. The anonymized data will appear on www.sqltoolkit.co.uk.

3.1. Sampling

Non-probability convenience sampling was selected to allow all those who were willing and able to participate in the survey. It is impossible to know the size and dispersion of the database-management and data-professionals population. Convenience sampling [9,10,14] is commonly used during preliminary research to gain a summary of interesting information. It allows the data to be collected quickly and inexpensively.

The sample was obtained through advertising the survey via social media such as Twitter, LinkedIn and Facebook groups, email newsletters and blog posts. A strategic decision was taken to gather data as widely as possible across the database population, to include a range
