We investigate the daily short-selling by foreign investors and their impact on stock price, liquidity, and volatility in the Korean stock market. From January 1, 2006, to May 31, 2010, we find that the majority of short-selling is performed by foreign, rather than by domestic, investors and that foreign short-sellers are contrarians, whose large short-selling predicts short-run future return. We also find that foreign investors’ short-selling is performed when buying-pressure is high, but does not improve stock liquidity. Furthermore, we find that foreign investors’ short-selling does not increase volatility, providing evidence against the foreign investors’ destabilizing role in emerging markets.

\section{1. Introduction}

In this paper, we investigate short-selling activities by foreign investors and their impact on stock price, liquidity, and volatility in the Korean stock market. Despite the vast amount of studies on short-selling in...
the US market, a few studies examine short-selling activity in the global financial markets other than in the US (Beber and Pagano, 2013; Bris et al., 2007; Chang et al., 2007; Charoenrook and Daouk, 2005; Jain et al., 2013; Safﬁ and Sigurdsson, 2011) or in American Depository Receipts from overseas markets (Blau et al., 2012). Hence, general features of foreign investors’ short-selling trading and its impact on stock characteristics have not been given much attention. Filling this gap, we contribute to the literature by investigating the following wide range of research questions: How much daily short-selling is carried out in emerging markets? Are foreign investors bigger players in short-selling markets than domestic investors, or vice versa? What short-selling trading strategies, on average, are used by foreign investors in emerging markets? Can we ﬁnd evidence that foreign investors are informed or naïve, uninformed trend-chasers through their short-selling activity? Do foreign short-sellers provide liquidity? Do foreign investors destabilize stock prices through their short-selling activity?

We focus on the Korean stock market for the following reasons. First, Korea has the most developed ﬁnancial market among emerging markets in which many foreign investors can actively trade under less binding regulations on foreign investors. For example, the legal limitation on share ownership by foreign investors was abolished in the Korean market before our sample period begins. Second, the Korea Exchange (KRX) provides high-frequency data with good quality for a relatively long period of time; Our sample period covers ﬁve and a half years, while Diether et al. (2009a) use only a one-year sample period. In addition, the presence of high-frequency data enables us to study daily short-selling activity and its relation with other variables of interests. Another beneﬁt of our dataset is that it distinguishes each trade by traders’ type. That is, each trade is tagged to denote whether it was initiated by domestic individual investors, domestic institutional investors, or foreign institutional investors. Hence, our data provides a good opportunity to examine different trading behaviors according to different investor types.1 The most prominent and unique feature of our dataset may be that each trade is tagged with order sequence number and the direction of trade, which shows whether it was buyer- or seller-initiated, rendering Lee and Ready’s (1991) algorithm for obtaining order imbalance data unnecessary for our sample stocks. This provides beneﬁt of constructing buy-order imbalance data without being engaged in the argument about the validity of Lee and Ready algorithm (Ellis et al., 2000; Odders-White, 2000).

In Korean stock market, short-selling is not so frequent compared to that in the US market. According to Diether et al. (2009a), 24% and 31% of daily trading volume is generated from short-selling trading in New York Stock Exchange and in Nasdaq, respectively, in 2005. However, for 761 stocks in Korean stock market, before any screening, we ﬁnd that the cross-sectional mean of average daily short-selling is only 0.53% of daily trading volume over the sample period from January 1, 2006 to May 31, 2010, excluding October 1, 2008, to May 31, 2009, when short-selling was banned in Korea by regulation. Moreover, for 24 percent of stocks, average short-selling is zero and 92% of stocks have an average short-selling of less than 2% of trading volume. Legal restrictions during our sample period on hedge funds, which often use short sales to carry out short strategies, may contribute to this small percentage of short-selling relative to trading volume in the Korean stock market.2 Given the rarity of short-selling in the Korean stock market, we restrict our sample to the 50 stocks that are mostly actively engaged in short-selling over the sample period, in order to perform meaningful analyses for short-sale trading activity.3 The average market capitalization of the ﬁfty sample stocks is 380,920 billion Korean won (roughly USD 346 billion),4 reﬂecting 47.8% of total market capitalization of all stocks listed in Korean stock market. In our sample, the mean short-selling volume in the Korean market is 3.16% of the daily trading volume.

Interestingly, we ﬁnd that the major portion of short sales is performed by foreign investors, whereas domestic investors, both individuals and institutions, are rarely engaged in short-selling trading in Korean stock market. Short-selling by individual and institutional domestic investors constitutes 0.05% and 0.24%,
