**HIGHLIGHTS**
- An equilibrium gasifier model is coupled to a detailed 1-D MEA model.
- Cell performance is greatly enhanced by sending H2O to the gasifier instead of CO2.
- Thermal coupling between the gasifier and fuel cell significantly raises efficiency.
- State-of-the-art efficiency is predicted for an indirect carbon fuel cell system.

**ABSTRACT**
An indirect carbon fuel cell (ICFC) system that couples coal gasification to a solid oxide fuel cell (SOFC) is a promising candidate for high efficiency stationary power. This study couples an equilibrium gasifier model to a detailed 1D MEA model to study the theoretical performance of an ICFC system run on steam or carbon dioxide. Results show that the fuel cell in the ICFC system is capable of power densities greater than 1.0 W cm\(^{-2}\) with H2O recycle, and power densities ranging from 0.2 to 0.4 W cm\(^{-2}\) with CO2 recycle. This result indicates that the ICFC system performs better with steam than with CO2 gasification as a result of the faster electro-oxidation kinetics of H2 relative to CO. The ICFC system is then shown to reach higher current densities and efficiencies than a thermally decoupled gasifier + fuel cell (G + FC) system because it does not include combustion losses associated with autothermal gasification. 55--60% efficiency is predicted for the ICFC system coupled to a bottoming cycle, making this technology competitive with other state-of-the-art stationary power candidates.

1. Introduction

Growing concern over greenhouse gas emissions has driven research into cleaner power production alternatives. However, even with progressive energy policies in place, the IEA projects a global rise in coal-fired power generation over the next few decades due to the industrialization of developing nations [1]. Clean coal technologies with higher system efficiency and CO2 capture are therefore necessary in the coming decades to mitigate harmful emissions. The carbon fuel cell (CFC) system is a promising candidate for highly-efficient coal power production that releases a diluent-free CO2 stream ready for capture and sequestration [2]. This paper focuses on a non-molten CFC system design that couples a ceramic solid oxide fuel cell (SOFC) to a gasifier [3].

Several bench-scale experiments and models have demonstrated the concept of this CFC system with CO2 as the gasification agent [4–6]. On the other hand, steam gasification has been largely neglected in previous work because it requires more pre-heating and it produces H2S, which quickly degrades SOFC performance [7]. However, steam has a couple of significant advantages over CO2 in a CFC system: 1) H2O gasification proceeds 2–6 times faster than CO2 gasification [8,9]; and 2) the H2 produced by steam gasification can be oxidized 2–3 times faster than CO is oxidized on the SOFC anode [10]. Therefore, there is a strong incentive to consider H2O as an alternative to CO2 in a CFC system to improve performance.

Two fundamental questions still need to be answered for this CFC system: 1) how much will system power density increase if steam is used instead of carbon dioxide as the gasifying agent?; and 2) how much will system efficiency increase when a gasifier is coupled to a SOFC? A preliminary CFC modeling study on this topic coupled an equilibrium gasifier to a SOFC with fixed voltage and...
current [11]. That study compared a few CFC systems with varying degrees of coupling between components, and used thermodynamic analyses to compare the performance of these systems with both CO₂ and H₂O. Although the paper gave a good overview of the different systems, it did not find an advantage of using H₂O over CO₂ because the model fixed cell voltage and did not include finite-rate kinetics for SOFC surface reforming and electrochemistry. Similarly, that thermodynamic analysis did not accurately assess the efficiency gained by thermal coupling because a finite-rate kinetic model is needed to accurately determine fuel cell efficiency.

This paper addresses these fundamental questions about the CFC system using an equilibrium gasifier model coupled to a 1D-MEA model with finite-rate kinetics. The gasifier can be modeled in equilibrium because it is in a separate compartment upstream of the SOFC stack and can therefore be sized to ensure sufficient residence time. The SOFC model, on the other hand, includes finite-rate kinetics in order to accurately compare the H₂ and CO electrochemical oxidation rates and assess the various losses in the cell. First the CFC system model is presented along with an explanation of the different CFC system classifications. Next the governing equations are presented for the gasifier and fuel cell components of the model. Finally, the two fundamental questions posed earlier are addressed sequentially with two modeling studies. The first study compares the impacts of H₂O and CO₂ gasification on system performance over a range of temperatures. The second study explores the impact of thermal coupling between the gasifier and fuel cell on system efficiency.

2. Model description

The objective of this model is to determine CFC system power and efficiency over a range of current densities and operating conditions. The combined CFC system is presented first, followed by descriptions of the equilibrium gasifier model and fuel cell model. The fuel cell model has been previously validated against experimental data for many syngas mixtures at 800 °C, and the governing equations of the model are described in detail elsewhere [12,13].

2.1. The CFC system model

2.1.1. System classifications

There is considerable debate over the proper terminology to describe CFC systems [14]. Table 1 breaks down the CFC system classification adopted here by the extent of coupling between the gasifier and SOFC. Systems listed higher are more coupled and theoretically capable of obtaining higher efficiencies, but at the expense of more complex integrated designs. The model in this paper focuses on the indirect CFC (ICFC) and gasifier + fuel cell
