Atrophic gastritis

### ABSTRACT

The paper presents a pilot research on the application of clinical decision support systems in a atrophic gastritis screening task. Two different DSS learning strategies have been tested – a standalone classifier and classifier ensemble application. Such classification algorithms as C4.5, CART, JRip and Naive Bayes were used as base classifiers. The classifiers were evaluated on the respondent medical data from an inquiry form, containing 28 attributes and 840 records. The dataset was preprocessed using simple methods in initial data analysis as well as more complex data mining methods for feature selection. The obtained results are summarized and discussed in order to summarize an information on what learning strategies are more applicable to the present dataset and should be studied in more detail in primary research.

### 1. Introduction

Cancer is the worldwide problem in social health and one of the leading causes of death. Nevertheless it is known that most of cancer types are treatable. Referencing the World Health Organization data, at least 40% of all local cancer types are treatable and can be prevented, avoiding the risk factors, common not only for cancer, but also for the most chronic diseases. These risk factors are well known and the most important of them are smoking, alcohol and other pernicious habits, activity shortage, adipositis (excessive weight) and different infectious agents. New medical technologies, new medicaments, vaccines, screening systems are continuously developed and introduced, all aimed at the identification and treatment of cancer at initial stages and the improvement of life quality and life length for patients with cancer.

Even though globally the gastric cancer incidence is declining and in many Western countries the disease is not considered among the major health issues any more, globally the cancer of the stomach is still continuing to be an important healthcare problem. Gastric cancer is remaining the second leading cause of mortality worldwide within the group of malignant diseases after the lung cancer, and is accounting for almost 10% of cancer related deaths. Among men gastric cancer is the second (after lung cancer), but among women – the third leading (after breast and lung) cause of cancer-related deaths (Su et al., 2007; WHO, 2013).

Gastric cancer is a very challenging malignancy given that it presents late, has complex pathogenetic mechanisms with multiple carcinogenic processes implicated, and is only moderately sensitive to chemotherapy and radiation. Gastric cancer presents mostly in an advanced stage and is lethal unless diagnosed early (Crew & Neugut, 2006; Miranda, Abelha, Santos, Machado, & Neves, 2009; Varadhachary & Ajani, 2005;).

The present paper discusses a possibility of application of CDSS – Clinical Decision Support Systems in order to give an expert additional information on probable disease; an atrophic gastritis in our case. Section 2 gives a look into CDSS, defines the main objectives of the system and reveals methods used in the pilot research. Section 3 presents the system evaluation results, which are summarized and discussed in Section 4.

### 2. Clinical decision support system

Clinical decision support systems (CDSS) are computer systems designed to support clinician decision making about specific patients at the point of time these decisions are made. Decision support systems have been incorporated in healthcare information systems for a long time, but these systems have usually supported retrospective analyses of financial and administrative data (Sauter, 2011). Recently, sophisticated data mining approaches have been proposed for similar retrospective analyses of both administrative and clinical data (Intarajak & Kang, 2009; Sauter, 2011), bringing new possibilities in designing efficient clinical decision support systems.

Barner and La Lande in Sauter (2011) propose a simple CDSS classification as knowledge-based and nonknowledge-based

85 systems. The primary difference pointed out was the ability to gener-  
86 erate and apply rules in knowledge-based systems with compari-  
87 son to the nonknowledge-bases systems that use such methods  
88 as artificial neural networks and genetic algorithms (Lisboa & Tak-  
89 tak, 2006; Romero, Valdes, & Barton, 2007; Velikova, Lucas, Ferre-  
90 ira, Samulski, & Karssemeijer, 2008). This CDSS classification is still  
91 applicable, but it should be pointed out that modern data mining  
92 approaches provide a wide range of possibilities to generate rules  
93 using ANN and GA (Galinina & Parshutin, 2011; Quteishat & Lim,  
94 2007). With respect to this classification the knowledge-based  
95 CDSS has been chosen for the present pilot research.

96 2.1. Concepts and objectives

97 The main objective of a clinical decision support system is to  
98 give an expert additional information in order to support an accu-  
99 rate diagnosis. The simplest way to reach this target considers  
100 solving the classification task. From this point of view, at least  
101 two types of CDSS can be defined – a binary DSS and a multi-class  
102 DSS. The multi-class DSS is oriented towards a multi-class classi-  
103 fication task; it receives a number of symptoms as an input param-  
104 eters and returns the most probable disease with such symptoms.  
105 The binary DSS is a subtype of a multi-class DSS; it is oriented to-  
106 wards a specific disease, receives input information the same way  
107 and gives an answer whether a patient has this specific disease or  
108 not.

109 As our pilot research focuses on a specific disease – atrophic  
110 gastritis, thus the application of binary CDSS structure was our  
111 choice. The main objectives of CDSS, as we see it, are ability to  
112 automatically process the input data – symptoms, inquiry data  
113 etc.; and return an information whether the input data is close to  
114 positive or negative result. To do so, the CDSS must have a knowl-  
115 edge base, manually constructed or created using a built-in learn-  
116 ing algorithm.

117 2.2. Methods

118 Medical informatics research has employed traditional statisti-  
119 cal methods, such as logistic regression and discriminant analysis,  
120 support vector machines, as well as learning methods, such as  
121 decision trees, neural networks and case-based reasoning (Chun,  
122 Kim, Hahm, Park, & Chun, 2008; Flouris & Duffy, 2006; Miranda  
123 et al., 2009; Lee, Lin, & Lee, 2006; Su et al., 2007; Vercellis, 2009).  
124 These methods are used individually or combined with other data  
125 mining methods.

126 There are two learning strategies compared in the present re-  
127 search. The first one consists in building a base classifier using a  
128 single classification algorithm. The most popular classification  
129 algorithms that are widely used are decision trees – C4.5 and  
130 CART; rule induction algorithms based on a Ripper algorithm and  
131 probabilistic algorithms as NB. Each of these algorithms will be  
132 evaluated and compared with others. An output of this learning  
133 strategy will be the prediction on the most probable class for a spe-  
134 cific descriptive data. An additional information can be obtained if  
135 a user-friendly algorithms are user, such as decision trees, giving a  
136 possibility to visualize the rules in the knowledge base.

137 Another learning strategy applies classifier ensembles. This  
138 technique constructs a set of base classifiers from training data  
139 and performs classification by taking a vote on the predictions  
140 made by each base classifier (Tan, Steinbach, & Kumar, 2006).  
141 The most popular techniques in this area are bagging and boosting.

142 Bagging (bootstrap aggregating) is a technique that repeatedly  
143 samples (with replacement) from a dataset according to a uniform  
144 probability distribution. Each bootstrap sample has the same size  
145 as the original data. Each bootstrap is used to built a base classifier.

146 Classification is made by taking a majority vote among the predic-  
147 tions made by each base classifier (Tan et al., 2006).

148 Boosting is an interactive procedure used to adaptively change  
149 the distribution of training examples so that the base classifiers  
150 will focus on examples that are hard to classify. Each training  
151 example is assigned a weight that may be adaptively changed at  
152 the end of each boosting round. Boosting can be applied to a single  
153 base classifier or combined with bagging (Tan et al., 2006).

154 This learning strategy additionally to the class prediction gives  
155 probabilities for each class, based on votes of each classifier in  
156 ensemble. Classifier efficiency rates, such as classification accuracy,  
157 false negative rate etc., can be used as weights, giving weighted  
158 class score. Eq. (1) can be used to calculate the score of the *j*th class.  
159 It is generalized equation where *j* is the class index, *w<sub>ij</sub>* – coeffi-  
160 cient of an *i*th of *k* classifier for the *j*th class and *L<sub>ij</sub>* if the binary  
161 function, returning 1 if classifier predicts class *j* and 0 otherwise.  
162 The weight *w<sub>ij</sub>* is linked to the class *j* because such coefficients  
163 as false negative rate differ for each class. In case if weight coeffi-  
164 cient does not differ upon the class, such as classification accuracy,  
165 Eq. (2) can be used.  
166

$$S_j = \frac{\sum_{i=1}^k w_{ij} * L_{ij}}{\sum_{i=1}^k w_{ij}} \tag{1}$$

$$S_j = \frac{\sum_{i=1}^k w_i * L_{ij}}{\sum_{i=1}^k w_i} \tag{2}$$

169 The final predicted class *C* will have the best score *S'*, which is cho-  
170 sen using Eq. (3).  
171

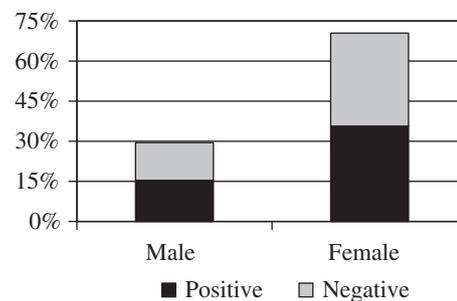

$$S' = \begin{cases} argmax(S_j), \forall C_j & w \rightarrow max \\ argmin(S_j), \forall C_j & w \rightarrow min \end{cases} \tag{3}$$

174 3. System evaluation

175 This section provides an information about the dataset used in  
176 experiments, describes the data preprocessing steps taken to pre-  
177 pare data (Section 3.1), gives a look into the experiments per-  
178 formed to evaluate the learning strategies (see Section 2.2) and  
179 shows the obtained results (Section 3.2).

180 3.1. Data description and preprocessing

181 Learning strategies were evaluated using respondent medical  
182 data, who filled the inquiry form. The initial dataset contained 28  
183 descriptive attributes and a binary target attribute denoting pos-  
184 itive or negative atrophic gastritis diagnosis. The target attribute  
185 values were obtained using the golden standard histological anal-  
186 ysis of a respondent tissue examples. In total, the initial dataset  
187 contained 840 records, having almost equal class proportions –  
188 430 (51%) positive records and 410 (49%) negative records. Fig. 1

189 Fig. 1. Class absolute proportions for male and female patients.
