Abstract

This study develops an empirical approach to measuring the monetary policy effectiveness for price stability based on stock market expectations. First, we use the fraction of fundamentalists estimated by the model of heterogeneous agents as an indicator of agents' predictions of stock market movements. When the expectations of fundamentalists are the only basis for interest rate policy decision making, our results in seven countries show that those with an overvalued stock price use tight monetary policy so that the price falls to the fundamental level, and countries with an undervalued stock price use expansionary monetary policy so the price increases to the fundamental level. Furthermore, the stock price in the next six months in these countries continues to show a negative reaction to expectations-based monetary policy. In addition, in countries not subject to the influence of monetary policy based on the expectations of fundamentalists, our survey results showed that within the next three months, in more than 33% of cases, stock prices reacted negatively to policy. In short,
