ABSTRACT

Purpose: The 2005 expansion of the Ethiopian abortion law provided minors access to legal abortions, yet little is known about abortion among adolescents. This paper estimates the incidence of legal and clandestine abortions and the severity of abortion-related complications among adolescent and nonadolescent women in Ethiopia in 2014.

Methods: This paper uses data from three surveys: a Health Facility Survey (n = 822) to collect data on legal abortions and postabortion complications, a Health Professionals Survey (n = 82) to estimate the share of clandestine abortions that resulted in treated complications, and a Prospective Data Survey (n = 5,604) to collect data on abortion care clients. An age-specific variant of the Abortion Incidence Complications Method was used to estimate abortions by age-group.

Results: Adolescents have the lowest abortion rate among all women below age 35 (19.6 per 1,000 women). After adjusting for lower levels of sexual activity among adolescents however, we find that adolescents have the highest abortion rate among all age-groups. Adolescents also have the highest proportion (64%) of legal abortions compared with other age-groups. We find no differences in the severity of abortion-related complications between adolescent and nonadolescent women.

Conclusions: We find no evidence that adolescents are more likely than older women to have clandestine abortions. However, the higher abortion and pregnancy rates among sexually active adolescents suggest that they face barriers in access to and use of contraceptive services. Further work is needed to address the persistence of clandestine abortions among adolescents in a context where safe and legal abortion is available.

IMPLICATIONS AND CONTRIBUTION

This assessment of legal and clandestine abortion among Ethiopian adolescents shows that adolescents have the highest proportion of legal abortions, suggesting a benefit to acknowledging adolescents in reproductive health policies. The high rate of abortion among sexually active adolescents indicates a need for promoting adolescent-targeted family planning services.

Conflicts of Interest: The authors do not have financial relationships with any organizations that might have an interest in the submitted work. They have no other relationships or activities that could influence or appear to have influenced the submitted work.

Abortion is one of the leading causes of maternal mortality worldwide [1,2]. The Government of Ethiopia has made considerable efforts to decrease abortion-related morbidity and mortality. In 2005, the abortion law was expanded to permit abortion in cases of rape, incest, and fetal impairment, to save the life of the woman, if the woman has a physical or mental disability, or if she is under 18 years of age [3]. Ethiopia is one of the few countries that explicitly acknowledge the difficulties young pregnant
women face and the need to decrease barriers to accessing abortion services among this age-group. Minors seeking abortions need neither parental consent nor any proof of age [3]. In 2006, the Ethiopian government made further efforts to expand the provision of legal and safe abortion services by developing and disseminating national guidelines for the provision of abortion care [3]. Under the law, legal abortions have increased from 27% of all abortions in 2008 to 53% in 2014 [4,5].

Despite the change in the law and expansion of services, young women in Ethiopia report uncertainty about the legality of abortion [6–8], and explicit knowledge that abortion is legal for minors is low [8,9]. Beyond gaps in knowledge, concerns about cost, privacy, and judgment from providers may create barriers in adolescents’ access to formalized services, leaving them particularly vulnerable to clandestine, and potentially unsafe, abortion [10,11]. Adolescents also confront the same barriers as older women to accessing safe abortion, including lack of information about location and availability of services, pressure from families and communities, poorly equipped facilities, absent providers, and a weak referral system [12,13]. Similar barriers have been identified as potentially limiting adolescents’ access to family planning services [14–16]. One-fifth of married adolescents and 40% of unmarried adolescents had an unmet need for family planning in Ethiopia in 2016 [17].

Research conducted in Ethiopia and elsewhere indicates that when adolescents pursue abortions, they often resort to unsafe methods or seek out abortion services at later gestations [10,18,19]. A study of abortion patients in one hospital in Ethiopia found that women under the age of 19 were twice as likely to have a second trimester abortion than older women [19]. Obtaining abortions at later gestations, and using less safe methods, may result in more severe abortion-related morbidities among adolescents [10].

Ethiopian adolescents are unique compared with other young women in the region in that they have official avenues available for legal and safe abortion. This paper assesses whether adolescents in fact benefit from the legal and safe abortion services. Detailed study protocols are described in Moore et al. and Gebrehiwot et al. [5,23]. Ethical approval was received for research on human subjects from the Ethiopian Ministry of Science and Technology and the Guttmacher Institute’s institutional review board.

The PDS included data on the age of abortion care clients in public and private facilities. Additional age-distribution data were provided from the two NGOs providing abortion services in the country, which together provide services to 36% of women receiving facility-based postabortion care or legal abortions [23].

We use the term legal abortion to refer to both legal abortion and postabortion care (PAC) services.
