12 Thermosensitive yolk-shell nanoparticles were developed as remote-controlled targeting drug delivery platform for multimodal imaging and combined therapy of cancer. The nanoparticles were fabricated using magnetic Fe<sub>3</sub>O<sub>4</sub> nanoparticles as photothermal cores, 13 thermo-responsive poly(N-isopropylacrylamide)-co-1-Vinyl-2-pyrrolidone p(NIPAM-co-NVP) as shells (Fe<sub>3</sub>O<sub>4</sub>-PNIPAM), with a hollow 14 space between the two layers for loading of chemotherapeutic drug. The magnetic iron oxide nanoparticle cores could absorb and transform 15light to heat efficiently upon the irradiation of near infrared (NIR) laser, resulting in the shrink of the PNIPAM shell and the release of 16 chemo-drugs. In vivo fluorescence/photoacoustic images demonstrated that Fe<sub>3</sub>O<sub>4</sub>-PNIPAM nanoparticles could accumulate in the tumor 17 after intravenous injection. Upon the irradiation of the NIR laser, DOX-Fe<sub>3</sub>O<sub>4</sub>-PNIPAM nanoparticles exhibited outstanding synergistic effect. 18 The tumor inhibition rate increased from 40.3% (DOX-Fe<sub>3</sub>O<sub>4</sub>-PNIPAM alone) and 65.2% (Fe<sub>3</sub>O<sub>4</sub>-PNIPAM +NIR) to 91.5%. The results 19 demonstrated that the NIR-responsive nanocarrier offers a novel strategy for cancer theranostics and combined therapy of cancer. 20

23

Magnetic iron oxide nanoparticles have attracted extensive 24interest in biomedical field due to low toxicity, good biocom-25patibility and high stability in physiological environment. With 26the unique magnetic properties, magnetic nanoparticles have 27been widely applied in drug targeting and delivery,<sup>1,2</sup> 28diagnosis,<sup>3,4</sup> therapy.<sup>5,6</sup> Recently, magnetic iron oxide has 29been used as photosensitive agent for photothermal therapy 30 (PTT). PTT is a newly emerging technique that employs NIR 31 absorbing materials to mediate the conversion of near-infrared 32 light into heat, and then leads to thermal ablation of cancer cells. 33 Many endeavors have been devoted to the research of NIR 34

absorbing materials such as gold-based nanomaterials,<sup>7–10</sup> 35 carbon-based nanomaterials,<sup>11–14</sup> transition metal dichalcogen- 36 ides (TMDCs),<sup>15–17</sup> and organic nanoparticles such as 37 melanin,<sup>18–20</sup> Perylene-Diimide.<sup>21</sup> Compared with those NIR 38 absorbing materials, magnetic iron oxide nanoparticles will be 39 prominent photothermal agents due to well biocompatibility, low 40 toxicity, targeting and magnetic resonance imaging. For 41 instance, Chu et al studied the photothermal effect of the 42 Fe<sub>3</sub>O<sub>4</sub> nanoparticles with spherical, hexagonal and wire-like 43 shapes for cancer therapy both in vitro and in vivo.<sup>22</sup> Chen et al 44 reported that highly crystallized iron oxide nanoparticles coated 45

Figure 1. Schematic illustration of the preparation of Fe<sub>3</sub>O<sub>4</sub>-PNIPAM yolk-shell nanocomposites and NIR-trigger drug release.

with a polysiloxane-containing copolymer could be used as effective mediators for photothermal therapy.<sup>23</sup> We had constructed carboxymethyl chitosan (CMCTS) stabilized Fe<sub>3</sub>O<sub>4</sub> nanoparticles with extremely low toxicity for in vivo tumor ablation.<sup>24</sup>

For cancer therapy, traditional chemotherapy suffers from 51several drawbacks such as poor solubility, non-specificity and 52adverse side effect. Smart drug delivery systems which are 53stimuli-responsive, such as thermosensitive microgels, provide 54 the great potential of specific treatment of cancer. With the 55external heating, the hybrids shrink and lead to the 56site-specific release of the loaded chemotherapeutic drug in 5758tumor. As one of the most common temperature-sensitive matrix, poly(N-isopropylacrylamide) (PNIPAM) exhibits 59good biocompatibility and suitable lower critical solution 60 temperature (LCST).<sup>25</sup> Below this critical temperature ( $T_C$ ), 61 the chains swell and the drug can be loaded. When above the 62  $T_C$ , the chains undergo collapse and the drug is discharged. 63

Herein, we fabricated yolk-shell structured particles based on 64 Fe<sub>3</sub>O<sub>4</sub> particles and stimuli-sensitive poly(N-isopropylacrylamide)-65 co-1-Vinyl-2-pyrrolidone (p(NIPAM-co-NVP)) matrix. Fe<sub>3</sub>O<sub>4</sub>-66 p(NIPAM-co-NVP) (defined as Fe<sub>3</sub>O<sub>4</sub>-PNIPAM) yolk-shell particles 67 with photothermal and thermo-responsive properties were useful in 68 imaging and chemo-photothermal therapy of tumor. The structure of 69 the particles was schematically illustrated in Figure 1. Thermorespon-70 sive Fe<sub>3</sub>O<sub>4</sub>@PNIPAM particles have been reported recently.<sup>26,27</sup> 71However, the reported thermoresponsive particles were prepared by 72 coating PNIPAM directly onto the surface of the Fe<sub>3</sub>O<sub>4</sub> instead of 7374 yolk-shell structure which could increase the loading capacity of drug 75by the interstitial space between the outer shell and the inner core. The 76 prepared nanocomposites exhibited favorable magnetic property and outstanding NIR optical absorbance, and thus offered the contrasts in 77 magnetic resonance imaging (MRI) and multispectral optoacoustic 78tomography (MSOT) imaging. Upon the irradiation of NIR laser, drug 79release obviously enhanced. Synergistic anticancer effect was 80 observed both in vitro and vivo experiment, indicating the potential 81 of the nanocomposites for specific therapy of cancer. 82

#### Methods (refer to the supplementary information for details) 83

Yolk-shell structured Fe<sub>3</sub>O<sub>4</sub>-PNIPAM nanoparticles were <sup>84</sup> synthesized and characterized. In vivo experiments were <sup>85</sup> performed in compliance with the Jiangsu University Animal <sup>86</sup> Study Committee's requirements for the care and use of <sup>87</sup> laboratory animals in research. <sup>88</sup>

#### Results

## Synthesis, characterization and thermosensitive property90of nanocomposite91

As illustrated in the transmission electronic microscopy 92 (TEM), the Fe<sub>3</sub>O<sub>4</sub> nanoparticles had a uniform size with an 93 average diameter of  $\sim 25$  nm (Figure 2, A, S1). When silica layer 94 was introduced onto the Fe<sub>3</sub>O<sub>4</sub> to form Fe<sub>3</sub>O<sub>4</sub>@SiO<sub>2</sub> nanopar- 95 ticles, these nanoparticles remained uniform shapes with the 96 mean diameter of ~65 nm (Figure 2, B, S1). The Fe<sub>3</sub>O<sub>4</sub>@SiO<sub>2</sub> 97 particles coated with thermosensitive layer had been confirmed 98 by TEM image (Figure 2, C). Thermosensitive layer thickness 99 was about 50 nm (Figure 2, C, S1). Figure 2, D revealed a 100 noticeable yolk-shell structure after SiO<sub>2</sub> layer was etched. The 101 formation the nanoparticles can also be verified by 102 thermo-gravimetric analysis (TGA). As shown in Figure S2a, 103 the weight loss of ~45% mainly attributed to the decomposition 104 of oleic acid on the surface of  $Fe_3O_4$ . With the coating of SiO<sub>2</sub>, the 105 weight loss decreased to about 25%. Then over 40% of weight loss 106 was found after the introduction of p(NIPAM-co-NVP). 107 The etching of SiO<sub>2</sub> further increased the weight loss to about 108 55%. The TGA results indicate the successful construction of the 109 yolk-shell structure. 110

 $Fe_3O_4$ -p(NIPAM-co-NVP) (defined as  $Fe_3O_4$ -PNIPAM) 111 yolk-shell particles showed the absorption at NIR region 112 (700 ~ 850 nm). Drug-loaded particles (DOX-Fe\_3O\_4-PNIPAM) 113 displayed a UV-vis absorption peak at 490 nm, which was the 114 characteristic of free DOX (Figure 3, *A*). The thermosensitive 115
