Abstract

Engineering design and system operating comprise highly innovative and knowledge-intensive tasks in the design of an eco-industrial park. Efficient information exchange and communication among distributed parties are very important for a business to succeed. Building a well-structured framework for data/information streamlining and processing is an urgent task in order to achieve further process simulation and optimization in the eco-industrial parks. This paper presents a study of ontological representation for an eco-industrial system, and its deployment on a knowledge-based software platform. The contributions of this work include: Firstly, an ontology model for the relevant chemical process is built relying on the ontological framework provided by OntoCAPE. Secondly, a surrogate modeling method is adopted and implemented for the industrial system. Finally, a Graphical User Interface (GUI), acting as an operating platform, is developed based on the proposed software architectural design. A case study is carried out to demonstrate the chemical process simulation and information query on this platform.

1. Introduction

Over the past decades, study of eco-industrial parks (EIP) has gained wide popularity in the scientific community. An EIP is defined as a community of neighboring businesses collaborating with each other, seeking enhanced environmental, economic and social performance [1]. An EIP system is a large-scale complex system, comprised of a great number of components from different operation levels, including units, processes, plants and networks [2]. Efficient collaboration between different sectors is the key to EIP success, which requires storing, sharing and processing a large amount of heterogeneous and dispersed data and information. In this scenario, traditional information technology may no longer be able to provide satisfying support. It requires a novel knowledge-based software system, which has two basic components: 1) a knowledge base containing generic domain knowledge and concrete facts specific to the considered case; 2) and an inference engine to process the knowledge and facts stored in the knowledge base, and to generate solutions for the cases at hand. It's obvious that building a valid knowledge base is crucial to the development of an EIP software system. Ontologies are emerging as a useful infrastructure for knowledge representation and sharing. During the past decades, the number of available ontology frameworks has increased rapidly, in particular for the engineering domain. At the earliest stage, *EngMath* was presented for mathematical modelling in engineering [3], *YMIR* was reported for representation of engineering design knowledge [4], and *PhysSys* was developed for modelling generic physical system [5]. Subsequently, ontologies for a wider domain, such as chemical process engineering [6-7], pharmaceutical engineering [8], were proposed and applied. Amongst the reported ontologies, *OntoCAPE* [9] is the most prominent and well-accepted framework for process engineering. Several of its extensions and applications have been reported [10-12]. Although many ontological frameworks are reported for certain engineering domains and applications, the ontology-based representation and simulation of a large-scale industrial park system have never been achieved. This paper presents an efficient approach for developing a Computer Aided Process Engineering (CAPE) software system for an EIP. *OntoCAPE* is adopted for knowledge base construction. An efficient surrogate modelling method is developed to describe the performance of complex industrial systems. A software architecture is designed, and a Graphical User Interface (GUI) is developed in order to perform process simulation and information query in the EIP.
