ABSTRACT

The objective of this study was to determine the association among different housing and management practices on the prevalence of lameness, hock lesions, and thin cows on US dairy operations. This study was conducted as part of the National Animal Health Monitoring System’s Dairy 2014 study, which included dairy operations in 17 states. Size categories were assigned as follows: small (30–99 cows), medium (100–499 cows), and large (≥500 cows). Trained assessors visited 191 dairy operations from March through July 2014 and recorded locomotion and hock scores (on a 3-point scale), and the number of thin cows (body condition score ≤2.25) from a total of 22,622 cows (average 118 cows per farm). The majority of cows (90.4%) were considered to be sound (locomotion score = 1), 6.9% were mild/moderately lame (locomotion score = 2), and 2.7% were severely lame (locomotion score = 3). Similarly, most cows (87.3%) had no hock lesions (hock score = 1), 10.1% had mild lesions (hock score = 2), and 2.6% had severe hock lesions (hock score = 3). A low percentage of cows (4.2%) were thin. Univariate comparisons were performed using PROC LOGLINK, which accounts for study design and weighting. Variables meeting the univariate screening criterion of $P < 0.20$ were eligible for entry into multivariable models. Statistical significance in the multivariable models was declared at $P < 0.05$. Large operations had a lower within-herd prevalence of cows with locomotion score ≥2 and locomotion score = 3 compared with small or medium-sized operations. Operations on which cows were kept primarily on pasture had a lower percentage of locomotion score = 3 than those housed in freestall or open/dry lot operations. The use of sand bedding was associated with a lower within-herd prevalence of locomotion score ≥2 than straw/hay or dry/composted manure as the primary bedding material. Sand bedding was also associated with a lower within-herd prevalence of locomotion score = 3 than other bedding types except for rubber mats or mattresses. Operations that housed cows in an open/dry lot had a lower percentage of hock score ≥2 and hock score = 3 than other housing types. Providing sprinklers for heat abatement and having a nutritionist balance rations for cows was associated with a lower percentage of thin cows. Results from this study highlight management practices that may reduce the prevalence of lameness, hock lesions, and thin cows on dairy operations in the United States.

Key words: dairy cow, lameness, hock lesions, body condition

INTRODUCTION

Lameness is a leading welfare concern in the dairy industry, mainly because lame animals are in pain (O’Callaghan et al., 2003; Rushen et al., 2007). The mean prevalence of lameness on dairies in the United States is reported to range from 13 to 55% (von Kesselerlingk et al., 2012; Hoffman et al., 2014; Cook et al., 2016), indicating that roughly a quarter to half of dairy cows in the United States are in pain. In addition to its impact on welfare, lameness has been shown to result in decreased milk production (Warnick et al., 2001; Juarez et al., 2003; Hernandez et al., 2005), reduced reproductive efficiency (Hernandez et al., 2001; Garbarino et al., 2004), and increased culling (Sprecher et al., 1997; Booth et al., 2004). Dairy characteristics, such as housing type, bedding material, and flooring design, have been shown to affect dairy cow lameness. Cows in compost barns have been shown to have a lower prevalence of lameness compared with cows in freestall barns (Lobeck et al., 2011). Similarly, cows that were housed in freestall barns with access to pasture had a lower prevalence of lameness compared with those housed in freestall barns with no access to pasture (17 vs. 39%;...
Herd sizes were defined as very small (1 to 29 cows), small (30 to 99 cows), medium (100 to 299 cows), large (300 to 499 cows), and very large (500 or more cows). Herds were categorized into states within the United States. The states were categorized into 2 regions: East (West: California, Colorado, Idaho, Texas, Washington; East: Indiana, Iowa, Kentucky, Michigan, Minnesota, Missouri, New York, Ohio, Pennsylvania, Vermont, Virginia, Wisconsin). Then, NASS used a sampling frame and selected a stratified random sample of dairy operations within each state to participate in the study.

MATERIALS AND METHODS

Study Design

The USDA’s National Agricultural Statistics Service (NASS) Cattle Report was used to determine states for inclusion in the NAHMS Dairy 2014 study (USDA, 2013), with the goal of including states that accounted for at least 70% of both dairy operations and dairy cattle in the United States. Seventeen states were chosen for inclusion in the study, representing 80.5% of dairy operations and 81.3% of dairy cows in the United States. The states were categorized into 2 regions (West: California, Colorado, Idaho, Texas, Washington; East: Indiana, Iowa, Kentucky, Michigan, Minnesota, Missouri, New York, Ohio, Pennsylvania, Vermont, Virginia, Wisconsin). Then, NASS used a sampling frame and selected a stratified random sample of dairy operations within each state to participate in the study. Herd sizes were defined as very small (1 to 29 cows),
